

WireMock

HTTP mocking and service virtualization for controlled dependencies during testing.

What WireMock is

WireMock creates simulated APIs to isolate unstable, unavailable, expensive or not-yet-built dependencies.

Stubs and matching

Stubs match requests and return controlled responses using method, URL, headers, query parameters and body.

Failure scenarios

Simulate 4xx/5xx, latency, timeouts and malformed responses to validate resilience.

Standalone or embedded

Run WireMock as JAR/Docker or integrate it into Java/JVM tests.

QA use

Use mocks for hard-to-reproduce conditions while keeping simulated versus real integration explicit.

Attention point

Stale mocks can hide real incompatibilities; combine them with contract and integration tests.

QA Tip

Use mocks for control and determinism without confusing simulation with real integration.
