

TestRail

Test management platform for organizing cases, planning runs, recording results and tracking quality.

What is TestRail?

TestRail centralizes test cases, executions, results and reporting. It replaces scattered spreadsheets with a structured repository and can combine manual testing with automation results.

Projects, sections and cases

A Project organizes work. Sections/Subsections group cases by modules such as Login, Catalog and Checkout. Test Cases can include preconditions, steps, expected results, priority, references and custom fields.

Test Run — execution

A Test Run selects cases for a specific execution such as a Release 3.0 Smoke. Testers record results, comments and evidence and can assign tests to team members.

Test Plan — multiple configurations

Test Plans group runs and are useful for matrices such as Chrome/Windows, Firefox/Windows and Safari/macOS or multiple devices/environments.

Milestones

Milestones organize important cycles such as releases or versions and help track progress and results for that milestone.

Jira and defect integration

TestRail can link requirements and defects and integrate with tools such as Jira. Jira manages work/issues; TestRail focuses on test planning, execution and traceability.

Automation, API and CLI

Automation results can be published through integrations, API or CLI. The framework executes tests; TestRail centralizes results, history and reporting.

Reporting and traceability

Dashboards and reports track passed, failed, blocked, not run, coverage and trends. References and integrations connect requirements, cases, executions and defects.

Getting started

Create or open a project, organize sections, write cases, create a Test Run or Plan, select cases, execute, record results/defects and review progress/reports.

Watch out

TestRail organizes the process but does not create a good strategy by itself. Repositories full of duplicated or outdated cases are expensive; review structure, reuse, coverage and relevance regularly.
