

Event-Driven Architecture

Testing systems that asynchronously produce and consume events.

Events

Producers publish events and consumers react without direct call coupling.

QA risks

Ordering, duplication, loss, delay, incompatible schema and partial processing are central risks.

Testing

Validate schema, idempotency, retry, DLQ, correlation and observable consumer effects.

Messaging

Kafka, queues and cloud services require strategy for data, observability and cleanup.

QA Tip

Test what happens when the same message arrives twice; idempotency is a classic risk.
