

Smoke Testing

A short set of critical checks used to decide whether a build is stable enough for further testing.

Purpose

Quickly detect blocking failures in essential functions before investing in broader execution.

Scope

Use a few high-value scenarios: access, core navigation, authentication, critical transaction and essential integrations.

When

After deployment, a new build, environment change or before regression/UAT.

Outcome

A critical-flow failure may justify blocking subsequent execution until the risk is understood.

QA Tip: Smoke should be fast, deterministic and focused on what could block further validation.
