

Metrics, Excel & Power BI

Quality indicators, responsible interpretation and dashboards for test and defect tracking.

Why measure quality

Metrics help observe trends, risk and delivery capability. They do not replace qualitative analysis and should not be used alone to measure individual productivity.

Test execution

Execution Progress = executed / planned. Pass Rate = passed / executed. Failed and Blocked should be analyzed separately because they represent different problems.

Defect metrics

Defect Aging tracks time open; Reopen Rate shows reopened defects; Defect Leakage observes defects escaping to later stages. Severity and Priority help segment risk.

Coverage

Requirement Coverage, Risk Coverage and Automation Coverage answer different questions. 100% of test cases executed does not mean 100% of the product was tested.

Excel for QA

Pivot tables, filters, conditional formatting, COUNTIF/COUNTIFS and XLOOKUP help consolidate results and build quick reports.

Power BI for QA

Power BI connects sources, transforms data with Power Query, models relationships and builds dashboards. QA can consume CSV, Excel, APIs and tool exports.

DAX and indicators

DAX creates measures such as Pass Rate and filtered counts. A measure should reflect a clear definition; the same KPI name may use different formulas across organizations.

Executive dashboard

A good dashboard highlights trend, risk and required action. Avoid chart overload. Show context, period, scope and metric definitions to reduce misinterpretation.

QA tip

A high pass rate can hide critical risk; show context together with the number.
