

Payment Testing

Cards, instant payments, bank slips, authorization, declines, timeouts, refunds and idempotency.

Payment flow

Checkout sends a payment intent to a gateway or acquirer, receives a response and must correctly reflect the result in the order.

Essential scenarios

Test approval, decline, invalid data, timeout, outage, repeated attempts, cancellation, reversal, refund and inconsistencies between payment and order.

Idempotency and duplicates

Repeating a call after a timeout must not charge the customer twice. Payment APIs often use idempotency keys to control this risk.

Security and evidence

Never expose full PAN, CVV, tokens or sensitive data in evidence. Use authorized test data and validate masking, logs and permissions.

When to use it

Use this knowledge when product risk, architecture or the delivery stage requires this type of validation. Confirm the goal, environment, required data and expected evidence before starting.

How QA applies it

Start from the behavior or risk to validate, prepare data and environment, execute the technique or tool reproducibly and capture evidence that helps the team understand the result.

QA tip

An approved payment without an order, or an order without a consistent payment, is an integration issue that deserves end-to-end investigation.
