

Spring Tools

Complete Installation & Setup

Beginner guide - from download to first use

Objective

By the end of this manual, you should be able to install the tool, validate the installation, perform the first functional use and recognize common errors. Do not skip validation steps: they confirm that each stage actually worked.

Before you start

A supported JDK is required. Spring Tools can be used as a standalone distribution or extension depending on the selected product.

Official download and documentation

Attention

Use only test environments, accounts and devices when a tool can capture traffic, run scans, modify infrastructure or access data. In corporate environments, follow your organization policies.

Open the correct terminal

On Windows, use CMD or PowerShell. On macOS and Linux, use Terminal. Run commands exactly as shown and press Enter after each line.

Windows - step by step

Install a JDK, download Spring Tools from the official Spring page and install/extract it.

Create a Spring Starter Project from the IDE.

macOS - step by step

Install a JDK and the official Spring Tools package/extension.

```
java -version
```

Linux - step by step

Install a JDK and use the official Spring Tools distribution/extension.

```
java -version
```

Validate the installation

1. java -version

```
java -version
```

Commands and configuration

1. Create a Spring Starter Project from the IDE.

PATH, environment variables and a new terminal

When an installer adds an executable to PATH or you configure a variable such as JAVA_HOME/ANDROID_HOME, close the old terminal and open a new CMD/PowerShell. Then repeat the version command. If multiple versions are installed, use where <command> on Windows or which <command> on macOS/Linux to identify the executable being used. Do not remove PATH entries without understanding their origin.

Create a safe test folder

For the first tests, use a simple folder with no production files, for example C:\Projects\qa-lab or ~/qa-lab. This makes generated files, virtual environments, logs and configuration easier to identify.

First use / functional test

1. Run the generated Spring Boot application and observe the startup log.

Run the generated Spring Boot application and observe the startup log.

Expected result

The project resolves dependencies and the Spring Boot application starts without configuration errors.

Troubleshooting

- Read the terminal error before repeating commands. Check PATH/environment variables, runtime version, permissions, system architecture and whether a new terminal was opened after environment changes.
- Command not found: confirm the installation directory is on PATH and open a new terminal.
- Wrong version: check whether another older runtime or executable appears earlier on PATH.
- Permission denied: use a user-writable project directory and follow the vendor permission guidance; do not blindly run everything as administrator/root.
- Corporate proxy/firewall: configure the package manager/tool according to your organization network policy rather than disabling security controls.
