

Regression Testing

Verification that changes did not introduce unintended effects in existing functionality.

When to run

After fixes, features, refactoring, configuration changes, integrations or significant releases.

Risk-based selection

Prioritize changed areas, critical flows, integrations, defect history, revenue, security and shared functionality.

Full vs selective

Full regression covers a broad suite; selective regression reduces scope based on impact and risk.

Automation

Stable, repetitive and critical scenarios are good automation candidates, with continuous suite maintenance.

When to use it

Use this knowledge when product risk, architecture or the delivery stage requires this type of validation. Confirm the goal, environment, required data and expected evidence before starting.

How QA applies it

Start from the behavior or risk to validate, prepare data and environment, execute the technique or tool reproducibly and capture evidence that helps the team understand the result.

QA tip

Efficient regression is not always running everything; it is selecting enough coverage for the change risk.
